Phase 5 retention comparison

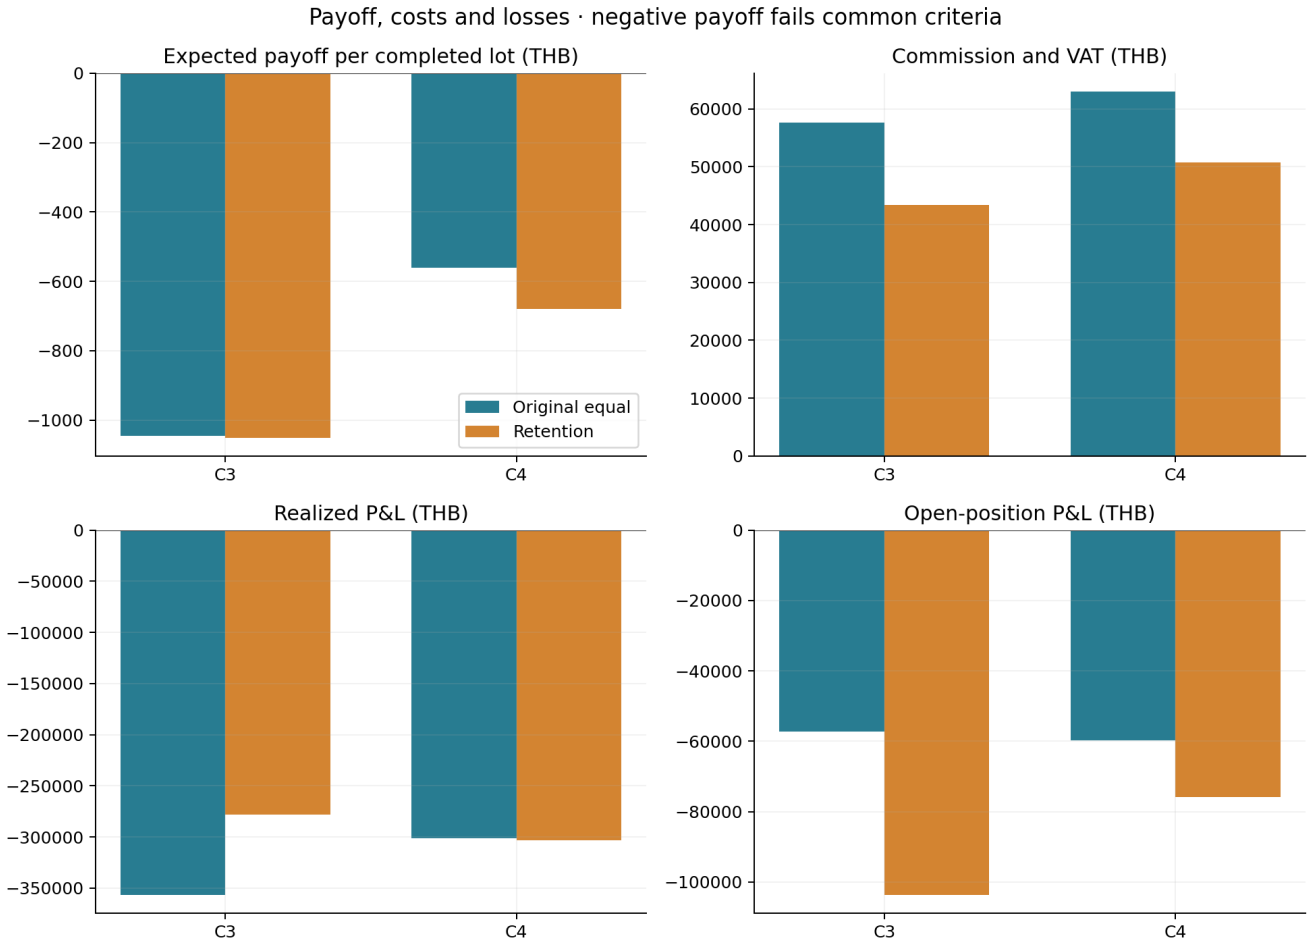

C3 and C4: original equal-weight controls and retention-only research variants. All runs use 16 September 2026 development sessions.

Both retention runs meet the exposure, round-trip and drawdown thresholds. Both still have negative expected payoff and negative total return, so neither passes common criteria or Best Alpha.

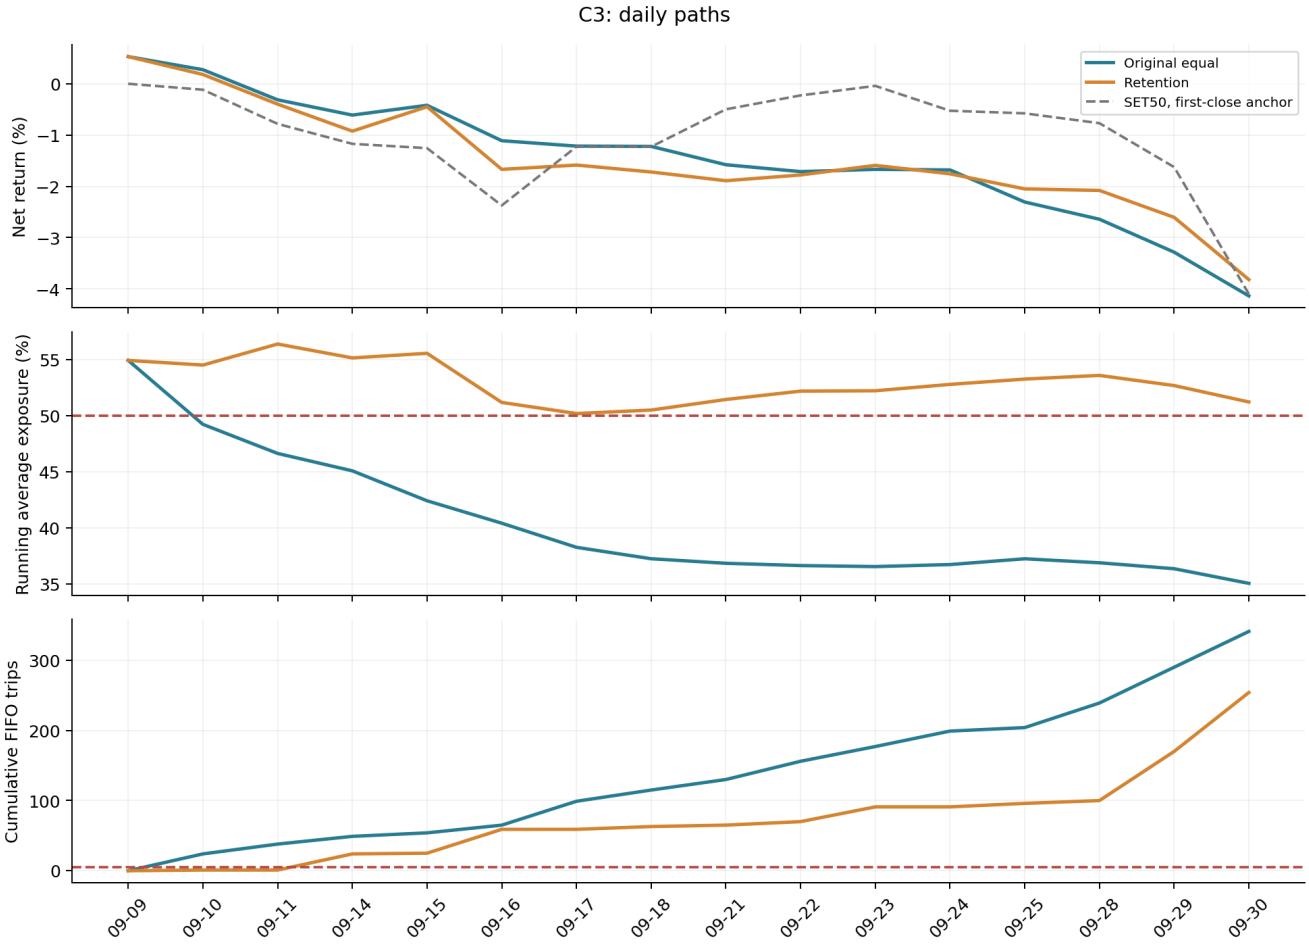

Costs and complete P&L

Fees fall in both retention runs, but open-position losses rise. Payoff is calculated on fully completed non-breakeven FIFO lots; partial fills can create multiple lots from a single position episode.

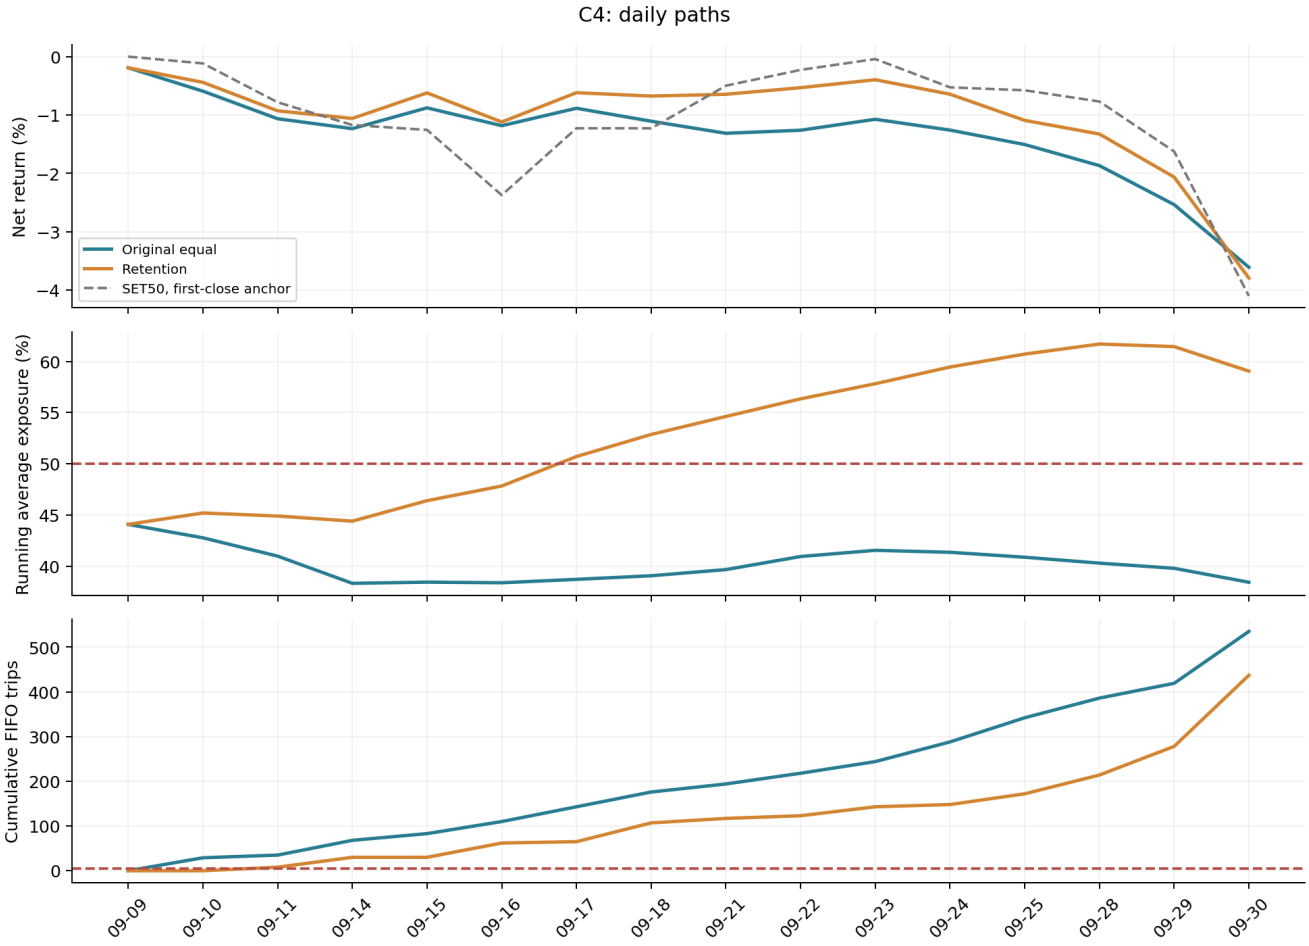

C3 daily paths

Return starts from initial cash; SET50 starts at its first sample close. Exposure is the running average of daily closes. The red lines mark the 50% exposure minimum and five FIFO lots.

C4 daily paths

Return starts from initial cash; SET50 starts at its first sample close. Exposure is the running average of daily closes. The red lines mark the 50% exposure minimum and five FIFO lots.

Interpretation and evidence

C3 retention improves net return by 0.318 percentage points but has a slightly worse payoff and a larger open loss. C4 retention worsens return by 0.185 points despite lower fees. Exposure increases by 16.17 and 20.60 percentage points respectively, so comparisons are not exposure matched.

The strategy retains opening quantities when entry eligibility fails; existing stops, profit exits, risk scaling and execution rules continue. Risk limits can drift, exits can be partial, and same-day restart state is not durable. No sample-end liquidation is forced.

All 32 strategy-days reconcile cash, holdings, fees, NAV and FIFO with the official engine. The targeted test confirms that a failed entry does not force a sale and a volatility stop can still sell. Results reuse September development data; additional permitted ticks and effective-dated membership are needed for independent validation. No candidate is promoted.
